## Paris Session 2022

## Experience with harmonics from PV

SCA2 P\$1, Question 1.2 What design and operation considerations should be included to optimise the selection of transformers for photovoltaic plant applications?

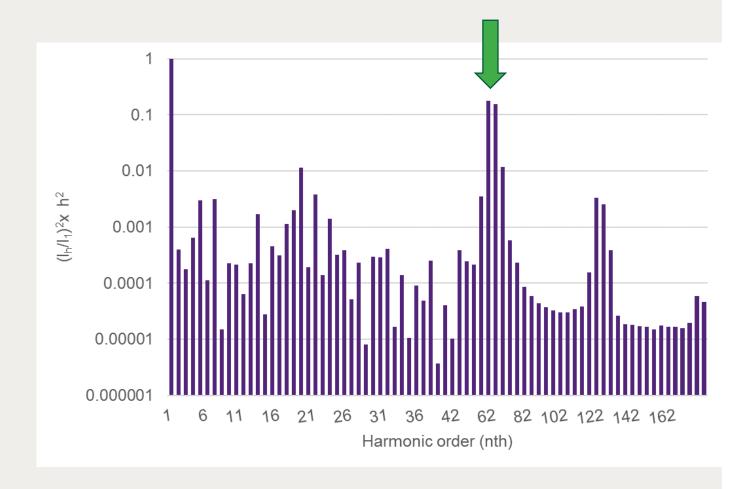

Jon Brown, Transpower (Speaker) and Dan Martin, ETEL (NZ); Firuz Zare, QUT and Matt Gibson, Ausgrid (Australia)

1

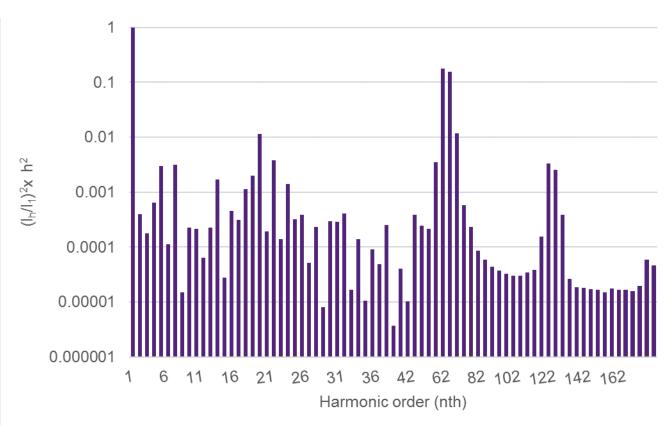

- The harmonics around a 1.4 MVA power transformer were investigated. The y-axis shows the heating effect of each harmonic normalised to the fundamental.
- The contribution of each individual harmonic on the loading factor is a function of the current<sup>2</sup> and frequency<sup>2</sup>.
- An unexpected surprise was the peaks at the 58<sup>th</sup> and 62<sup>nd</sup> harmonic, together they had a combined effect of 33%.
- Most utilities only measure harmonics up to the 50<sup>th</sup> order, yet this figure shows higher frequency harmonics being significant.

Data provided by Prof. Zare & Dr. J. Yaghoobi

- In total, the harmonics increased losses in transformer by 2% at this load.
- This caused a maximum calculated 2
  °C increase in hotspot temperature at
  this load.
- Our current recommendation is to measure high frequency harmonics and have analysed their impact on the insulation. At present, these high frequency harmonics are not well understood.

**Group Discussion Meeting** 

## Design considerations

- The harmonic content needs to be known (quite often the purchaser can't provide an accurate spectrum). A manufacturer can recommend derating a transformer, but this can result in higher no-load loss.
- Consider using a normal cyclic rating matched to the generator, rather than peak load. This will require transformer components to be rated properly.
- If the insulation is to be run hotter then consider a natural ester rather than mineral oil.
